SAS-Extract. 2020-07-14 18:06:24.518 PM - Linux servers are mostly built to be extremely stable, long-living computers. They are created to use hardware and software that is not designed for instability, and it shows. The infrastructure at Amazon is built on two core principles: You don't pay for resources you don't use, and you get the best computer hardware that money can buy. This isn't a marketing slogan; it's how we do things, and it's how we run our servers. You don't pay for resources you don't use, so you can run thousands of servers on a few machines. You don't pay for the best computer hardware money can buy, so you can use less hardware and more software. You don't pay for resources you don't use, so you can run large applications in small environment. The first core principle is that you should use only what you need. That's why we've enabled data depots for each of our data centers. They contain all the data and compute capacity that a customer requires, so that you don't have to pay for data you don't use. "Small" is relative. If you use a data center for only a few hours a week, you'll pay based on that usage. If you run a full-time environment, you'll pay for usage throughout the year. The second principle is that we build the best infrastructure possible for the price. We don't build systems where we have to upgrade the hardware regularly to avoid maintenance and ensure security. As a result, our infrastructure is always running well above the best price/performance numbers you can find. As a result, we can run large applications without a large budget. We've built our infrastructure to be very secure, and we don't provide any software outside of the standard Linux operating system. Our infrastructure is built on systems running Red Hat Enterprise Linux (RHEL), and we operate on a service-level agreement that ensures that your applications will always run at peak performance. This is how you get an 4bc0debe42
